1. Introduction 14

15 Olson (1965) was among the first to formally pose the puzzle of group formation and cooperation, and this has provoked a large 16 17literature seeking to understand group behavior. In this note, we introduce two incentive mechanisms to sustain intra-group coopera-18 19 tion with prisoner's dilemma payoffs. For simplicity, we examine three-agent groups where relations may either be triadic-one person 2021 interacting with two others-or tripartite, where all agents interact. 22 Due to shirking incentives, sustained group cooperation requires a system of endogenous enforcement. We posit a reward structure 23based on a transfer system and a punishment structure based on 24collective punishment. Both can ensure cooperation. 25

There is an existing literature that seeks to model institutions and 26 social networks in terms of endogenous enforcement. The use of 27 incentive slackness in triadic relations to tie strategies across two party 28 games or "domains," has been studied by Aoki (2001) and Bernheim and 29 Whinston (1990) while exogenous superior information or enforcement 30 31 capability among group members compared to non-group members is used in Fearon and Laitin (1996) and Ghatak and Guinnane (1999). 32 Moreover, such an institutional arrangement may itself be endogenous 33

In this note, we introduce two distinct incentive mechanisms that support dynamic intra-group cooperation in the context of prisoner's dilemma payoffs: rewards for cooperating, and punishments for defection, where the rewarding or punishing party may be outside the relationship.

45

(Okada, 1993). The model here takes the former approach, but we add to 34 the literature in two ways. First, we use transfers to endogenize the 35 amount of incentive slack. Second, our punishment mechanism extends 36 the use of incentive slack to three-party settings. 37

Tripartite cooperation has also been examined in Hart and Kurz 38 (1983) and Ray and Vohra (1999). While both papers seek to 39 endogenize the process of coalition formation, the latter goes a step 40 further in endogenizing the coalition structure. Our note differs from 41 these papers in that we do not assume that binding contracts can be 42 written. An application in this vein, where contracts are assumed to 43 bind, is the trade bloc model of Burbidge et al. (1997). 44

2. Analytical framework

The environment is comprised of a group with three agents, which 46 are represented by the set $A = \{1, 2, 3\}$. Each individual *i* possesses a 47 strategy set S_i , with $S' = S_1 \times S_2 \times S_3$. Let $q_i \in S_i$ be a feasible action for 48 player *i* in the stage game, and denote $q = \{q_i, q_j, q_k\}$. Choices are 49 perfectly observable, and players have perfect recall. A pure strategy 50 for a player *i* is thus a sequence $\{s_{i,t}(\cdot)\}_{t=1}^{\infty}$ mapping the history H_{t-1} of 51 previous action choices to the action choice in period *t*, $s_{i,t}(H_{t-1}) \in S_i$; 52 with the set of all such pure strategies given by Σ_i . These pure strategy 53 profiles induce an outcome path $Q(s) = \{q_t\}_{t=1}^{\infty} = \{q_{1,t}, q_{2,t}, q_{3,t}\}_{t=1}^{\infty}$. 54

These agents interact in bilateral relationships over an infinite 55 horizon (or, alternatively, over a finite horizon with no known 56 termination time). These relationships are summarized in Fig. 1. 5758

Agents have individual welfare given by

$$V_{i,0} = \sum_{t=0}^{\infty} (\delta_i)^t v_{ij,t} (q_{i,t}, q_{j,t}, q_{k,t}; \beta_{i,jk,t}),$$

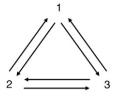

Fig. 1. Agent relationships.

60 where $V_{i,0}$ is the date 0 payoff to agent *i* given the agent's own action 61 $q_{i,t}$ and those of the other players $q_{j,t}$ and $q_{k,t}$, which result from the 62 strategies $s_{i,t}$, $s_{j,t}$, and $s_{k,t}$ employed at time *t*, respectively; $0 < \delta_i < 1$ is 63 *i*'s subjective discount rate; and $\beta_{i,jk,t}$ is a measure of the external 64 benefit accruing to *i* for a relationship between individuals *j* and *k* at 65 time *t*.

In the prisoner's dilemma, let $s_{i,t} = \{c,d;c,d;\tau_{ij};\tau_{ik}\}$, where $\tau_{ij}(\tau_{ik}) \ge 0$ is a transfer from *i* to *j* (*i* to *k*). $v_{ij}(d,c) > v_{ij}(c,c) > v_{ij}left(d,d) > v_{ij}(c,d)$ and similarly for the state game between *i* and *k*. Therefore, strategy *d* (*c*) is defection (cooperation) and the payoff structure does not depend on time.

Assumption 1. *Nash reversion strategy* Agents employ the *Nash reversion strategy* in the group formation game for the infinite horizon. In other words, a player *i* plays a strategy s_i along the equilibrium path Q (s) until one of the three players defects, and the Nash equilibrium of the stage game $q_{it} = \{d; d; \tau_{ii} = 0; \tau_{ik} = 0\}$ is played thereafter.

This trigger strategy is fairly standard in the literature, but here we assume that if even if just one player deviates, all players–even those who have not experienced deviation directly in the prisoner's dilemma–revert to the static Nash equilibrium. In addition, we have included the cessation of transfers as well as the corresponding flows of external benefits.

82 There is experimental evidence that Nash reversion strategies are employed in repeated game settings, including the prisoner's dilemma, 83 for two person games at least (Engel-Warnick and Slonim, 2004; Selten 84 and Stoecker, 1986). Nash reversion also allows us to show equilibrium 85 existence for the strongest threat possible; if a cooperative equilibrium 86 87 does exist, one can always look for lighter punishments to support it. We 88 will say that group formation is sustainable if all agents cooperate pairwise in their prisoner's dilemmas. 89

Definition 1. A subgame perfect pure strategy Nash equilibrium in the three-player game is a triple { q_1^*, q_2^*, q_3^* } induced by a profile $s = (s_1^*, s_2^*, s_3^*) \in \Sigma_1 \times \Sigma_2 \times \Sigma_3$ such that for every h_{t-1} the restriction $s|h_{t-1}$ to the subgame starting at *t* satisfies: $\forall i, j \in A, i \neq j$: { $s_i^* \neq s_i^*$ such that $V_i(s_i|h_{t-1}, s_j^*|h_{t-1}, s_k^*|h_{t-1}) > V_i^*(s_i^*|h_{t-1}, s_j^*|h_{t-1}, s_k^*|h_{t-1})$].

95 We now introduce the central proposition of this note.

Proposition 1 (Group formation). For $0 < \delta_1$, δ_j , $\delta_k < 1$ and $A = \{1, 2, 3\}$, there exist Nash reversion strategies involving rewards and punishments such that group formation is sustainable even when one or more incentive compatibility constraints in the bilateral prisoner's dilemma are violated.

101 **Proof.** See Appendix A.

Remark. The result for group formation above is relatively comprehensive. That is, if the conditions in Proposition 1 are satisfied such that the equilibrium in Definition 1 exists, then incentive constraints can even be violated for *both* players in the same prisoner's dilemma.

The proposition thus allows us to assert that, with appropriate Nash reversion strategies, group formation in the context of a game with bilateral prisoner's dilemma payoffs can be sustained even if any two agents meeting alone would not cooperate. This extra cooperation is sustained either due to a transfer rewards system–carrots–or collective punishment threats–sticks. For example, if agent 3 enjoys an external benefit from cooperation 112 between 1 and 2, he or she can make 1 internalize this by paying 1 a 113 transfer in every period as long as 1 cooperates with 2. If cooperation 114 ceases, so does the transfer. This is essentially a repeated contingent 115 use of the Coase theorem. Alternatively, though 2 and 3 may both be 116 tempted to defect on each other, the threat that–if that were to occur– 117 1 will defect on both of them in a collective punishment (and hence 118 remove their surplus from their interactions with 1), can remove the 119 temptation. 120

3. Applications

We offer two applications: Rewards in criminal gangs, and 122 discipline within military platoons.

Given the high risks involved in gang participation, the finding 124 that street-level members of gangs often earn more or less the mini- 125 mum wage presents a puzzle (Levitt and Venkatesh, 2000). Even after 126 taking into account the discounted value of potential future earnings- 127 given the tournament structure of gang participation-membership in 128 a gang appears to be suboptimal, especially given the likelihood that 129 criminal discount rates are relatively high (Paternoster and Brame, 130 1998).

However, the enforcement of the cooperative outcome in gangs 132 appears to be bolstered by rewards offered for cooperative behavior. 133 These rewards may be monetary (a larger share of crime-related 134 profits), nonpecuniary (enhanced recognition from promotion up 135 the gang's hierarchy, or a greater sense of belonging), or both. In 136 addition, these rewards usually accompany circumstances where 137 group cohesion may be threatened. For example, Klein (1995) dis- 138 cusses how members of street gangs enjoy enhanced cohesion after 139 engaging in sporadic criminal or violent activity, while Decker and 140 van Winkle (1996) document how proceeds from the sale of drugs are 141 considered rewards that are a part of street culture. These can be 142 viewed as ex post transfers to members, offered by the gang leader, in 143 exchange for the external benefits-usually viewed as leaders' 144 prestige-that he or she obtains as a result of the gang's continued 145 existence. 146

Punishment in the military is often meted out to the entire group. 147 Ostensibly, this is to build a sense of group "intermindedness," or more 148 precisely, a sense of unity through social solidarity (Spindler, 1948). 149 This is especially cogent in boot camp–where recruits are transitioning 150 from civilian to military life–and in paramilitary organizations (Archer, 151 1999), where looser institutional structures make it harder to prevent 152 desertion. 153

Such punishment allows military organizations to support group 154 cooperation, since punishments for deviant behavior in the 155 platoon target the collective for the transgressions of any one soldier. 156 For example, mass punishments remain common in boot camps 157 even though the practice is expressly prohibited by military law 158 (Heckathorn, 1988). In terms of our model, collective punishments of 159 this form ensure that compliance rapidly emerges in the platoon. 160

Appendix A

161 162

121

Proof of Proposition 1. Before proceeding with the proof, it is useful 163 to establish the following lemma. 164

Lemma 1 (Folk theorem). $\exists \delta_i < 1$ such that for any $\delta_i \in [\delta, 1]$ $\forall i, a \ 165$ cooperative outcome path $Q = \{\overline{q}_{i,b}q_{k,l}\}_{t=1}^{\tau} = \{c,c\}_{t=1}^{\tau}$ can be sustained with 166 the Nash reversion strategy, where $\underline{\delta}$ is the lowest discount factor that 167 can sustain cooperation, given the payoffs V_{ij} .

Proof. The lemma is a direct result of the Folk Theorem for repeated 169 games applied to the context here; see Fudenberg and Maskin (1986) 170 for a formal treatment.

<u>ARTICLE IN PRESS</u>

Lemma 2 shows the proposition when we allow for both transfers and spillovers from relationships. Lemma 3 shows the special case when there are no spillovers and no transfers, and only the stick mechanism–Nash reversion by all three players following a single defection–sustains cooperation.

Lemma 2. In the group formation game, there exist Nash reversion strategies with transfers $\tau_{ij} > 0$, $ij = \{1, 2, 3\}$, $i \neq j$ such that group formation is sustainable, even if one or more incentive compatibility constraints are violated inpairwise games in the absence of transfers, provided $\delta_i > 0$ and $\beta_{i,jk} > 0$ are sufficiently large or $\delta_i > 0$ and the incentive slack of one of the players in a different relationship are sufficiently large.

Proof. Even with the Nash reversion strategies, not all agents may be willing to play the prisoner's dilemma with both the other agents. However, we can develop the proof for the full cooperation case and then specialize it. Using $\tau_{ij} = -\tau_{ji}$, a nonempty set { $\tau_{12}, \tau_{13}, \tau_{23}$ } that satisfies the following conditions are sufficient for the Nash equilibrium:

$$\begin{array}{l} \nu_{12}(d,c) - \nu_{12}(c,c) + \nu_{13}(d,c) - \nu_{13}(c,c) < \frac{\delta_1}{1 - \delta_1} \\ \times \{ [\nu_{12}(c,c) - \nu_{12}(d,d)] + [\nu_{13}(c,c) - \nu_{13}(d,d)] + (\beta_{1,23} - \tau_{12} - \tau_{13}) \}, \end{array}$$
(A.1a)

$$\begin{split} & \nu_{21}(d,c) - \nu_{21}(c,c) + \nu_{23}(d,c) - \nu_{23}(c,c) < \frac{\delta_2}{1 - \delta_2} \\ & \times \big\{ [\nu_{21}(c,c) - \nu_{21}(d,d)] + [\nu_{23}(c,c) - \nu_{23}(d,d)] + \big(\beta_{2,13} + \tau_{12} - \tau_{23}\big) \big\}, \end{split}$$
 (A.1b)

$$\begin{split} & v_{31}(d,c) - v_{31}(c,c) + v_{32}(d,c) - v_{32}(c,c) < \frac{\delta_3}{1 - \delta_3} \\ & \times \left\{ [v_{31}(c,c) - v_{31}(d,d)] + [v_{32}(c,c) - v_{32}(d,d)] + \left(\beta_{3,12} + \tau_{13} + \tau_{23}\right) \right\}. \end{split} \tag{A.1c}$$

193

 $1-\delta_2$

221

Without loss of generality, assume that $\beta_{1,23}$ is large and that Eq. (A.1a) 194 is satisfied, but Eqs. (A.1b) and (A.1c) are not. Then there potentially exist 195 values of the transfers τ_{12} and τ_{13} such that the direction of the inequalities 196 in Eqs. (A.1b) and (A.1c) reverse, while the inequality in Eq. (A.1a) remains 197unchanged. This requires $\hat{\tau}_{12} + \hat{\tau}_{13} < \beta_{1,23}$, where $\hat{\tau}_{ij}$ denotes the minimum 198required transfer to sustain cooperation between *i* and *j*. The bound on 1's 199willingness to subsidize the game between 2 and 3 depends on the 200external benefit, $\beta_{1,23}$, he or she enjoys, given cooperation between 2 and 201202 3. Notice that if Eq. (A.1b) (if Eq. (A.1c)) is also satisfied, then the lower 203bound of $\beta_{1,23}$ can be lower, since $\hat{\tau}_{23}$ may be positive (negative).

However, not all players may be willing to play the prisoner's dilemma with each other. For example, if 1 and 3 do not play the prisoner's dilemma, then Definition 1 can still be satisfied with $\beta_{2,13}=0$ so that Eq. (A.1a) simplifies to

$$v_{12}(d,c) - v_{12}(c,c) < \frac{\delta_1}{1 - \delta_1} \left\{ \left[v_{12}(c,c) - v_{12}(d,d) \right] + \beta_{1,23} - \tau_{12} - \tau_{13} \right\},$$
(A.2a)

$$v_{21}(d,c) - v_{21}(c,c) + v_{23}(d,c) - v_{23}(c,c)$$

$$< \frac{\delta_2}{\delta_2} \{ [v_{23}(c,c) - v_{23}(d,d)] + [v_{23}(c,c) - v_{23}(d,d)] + \tau_{13} - \tau_{23} \}$$
(A.2b)

v₃₂(d, c)-v₃₂(c, c)<
$$\frac{\delta_3}{1-\delta_3}$$
 {[v₃₂(c, c)-v₃₂(d, d)] + $\beta_{3,21}$ + τ_{13} + τ_{23} }. (A.2c)

Again without loss of generality, for $\beta_{1,23}$ large, Eq. (A.2a) is satisfied and transfers can be used to satisfy the other equations, again up the value of the external benefit 1 enjoys. If, furthermore, 1 and 2 do not play the prisoner's dilemma so that $\nu_{12}(\cdot)=\nu_{21}(\cdot)=0$, Definition 1 simply requires

$$\beta_{1,23} > \tau_{12} + \tau_{13},$$
 (A.3a)

$$v_{23}(d,c) - v_{23}(c,c) < \frac{\delta_2}{1 - \delta_2} \{ [v_{23}(c,c) - v_{23}(d,d)] + (\tau_{12} - \tau_{23}) \},$$
(A.3b)

$$v_{32}(d,c) - v_{32}(c,c) < \frac{\delta_3}{1 - \delta_2} \{ [v_{32}(c,c) - v_{32}(d,d)] + (\tau_{13} + \tau_{23}) \},$$
(A.3c)

which again is satisfied for sufficiently large $\beta_{1,23}$. The cooperation 224 conditions for all other configurations of agents playing the prisoner's 225 dilemma are analogous.

Lemma 3. For $0 < \delta_i < 1$, $i = \{1, 2, 3\}$, there exist Nash reversion strategies 227 with punishments such that group formation is sustainable, even if one or 228 more incentive compatibility constraints are violated, provided every 229 player has incentive slack in at least one relationship and that $\delta_i > 0$ is 230 sufficiently large. 231

Proof. To remove the possibility of the transfer mechanism sustaining 232 cooperation, assume that $\beta_{i,jk} = \tau_{ij} = 0 \forall i, j, k$. If both of an agent's 233 incentive compatibility constraints are violated, by Lemma 1, the 234 agent will not cooperate. Therefore, we consider only cases with at 235 most one of each agent's incentive constraints violated. In this case, 236 group formation could still be possible as the Nash equilibrium. 237 Without loss of generality, let $v_{12}(c,c) = v_{12}(c,c) = \frac{\delta_1}{1 - \delta_1} [v_{12}(c,c) - v_{12}(d,d)]$ 238 and $v_{13}(d,c) - v_{13}(c,c) < \frac{\delta_1}{1 - \delta_1} [v_{13}(c,c) - v_{13}(d,d)]$. Given Nash reversion 239 group formation requires 240

$$\begin{split} & \nu_{12}(d,c) - \nu_{12}(c,c) + \nu_{13}(d,c) - \nu_{13}(c,c) \\ & < \frac{\delta_1}{1 - \delta_1} \{ [\nu_{12}(c,c) - \nu_{12}(d,d)] + [\nu_{13}(c,c) - \nu_{13}(d,d)] \}, \end{split}$$

$$\begin{split} & v_{21}(d,c) - v_{21}(c,c) + v_{23}(d,c) - v_{23}(c,c) \\ & < \frac{\delta_2}{1 - \delta_2} \{ [v_{21}(c,c) - v_{21}(d,d)] + [v_{23}(c,c) - v_{23}(d,d)] \}, \end{split}$$

$$\begin{array}{l} \nu_{31}(d,c) - \nu_{31}(c,c) + \nu_{32}(d,c) - \nu_{32}(c,c) \\ < & \frac{\delta_3}{1 - \delta_3} \{ [\nu_{31}(c,c) - \nu_{31}(d,d)] + [\nu_{32}(c,c) - \nu_{32}(d,d)] \}, \end{array}$$

246

252

and Eq. (A.4a) can still be satisfied for $v_{13}(c,c)$ sufficiently large. If both 247 Eqs. (A.4b) and (A.4c) are satisfied in an analogous manner, then group 248 formation is possible.

Taken together, Lemma 2 and 3 exhaust all possible cases, which 250 concludes the proof of the proposition. \Box 251
